## *The Ideal Gas Law

Bx Shawn P. Shhieldse, Ph. B.

## *Becall: Characteristics of Gases

*Gases do not have a fixed volume nor a fixed shape.
*Gases are described in terms of four macroscopic observables:
*Pressure
*Temperature
*Volume
*Moles of gas
*Becall: Characteristics of Gases
*The early gas laws described these macroscopic observables or characteristics relative to each other, but none of them put all of the "observables" together in one equation.
*Boyle's law related the pressure and volume of a gas at fixed $T$ and $n$.
*Charles's law related the temperature and volume of a gas at a fixed $P$ and $n$.

* Avogadro's law says one mole of any gas at STP ( $0^{\circ} \mathrm{C}$ and 1 atm ) will take up a volume of 22.4 L .

## *Ideal-Gas Law

So, let's continue developing the reasoning for the Ideal Gas Law!
-
Boyle's Law says the pressure of a gas is inversely related to its volume.

$$
(V \propto 1 / P)
$$

Charles's Law determined that the temperature of a gas and its volume or directly proportional.

$$
(V \propto T)
$$

Avogadro's Law demonstrated that the volume of a gas is directly proportional to the number of moles of the gas. $(V \propto n)$

## *Ideal-Gas Law

Combining all three laws, we get

$$
V \propto \frac{n T}{P}
$$

But, we need a "proportionality constant" to be able to use our relationship for calculating $V, n, P$, or $T$ !

## *Ideal-Gas Law

The gas constant, $R$, represents this proportionality.

$$
\mathrm{R}=0.08206 \frac{\mathrm{~L} \mathrm{~atm}}{\mathrm{~mol} \mathrm{~K}}
$$

**For the gas laws, we will only use this one.
Be sure to convert $V, T$, and $P$ into these units!**

## *Ideal-Gas Law

- Using R, we now have

$$
\begin{gathered}
V=R \frac{n T}{P} \quad \text { Or............... } \\
P V=n R T \\
\text { Aka "PiV-NeRT" }
\end{gathered}
$$

NOTE: You do not need to be able to derive the IG equation.

## *Example: The Ideal-Gas Law

When solid calcium carbonate $\left(\mathrm{CaCO}_{3}\right.$ is heated, it decomposes into solid calcium oxide $(\mathrm{CaO})$ and carbon dioxide gas $\left(\mathrm{CO}_{2}\right)$ according to the reaction given below. A small sample of $\mathrm{CaCO}_{3}$ is heated, and the carbon dioxide that evolves is collected in a $125-\mathrm{mL}$ flask. The gas collected in the flask has a pressure of 1.95 atm at a temperature of $45{ }^{\circ} \mathrm{C}$. How many moles of $\mathrm{CO}_{2}$ gas were produced?

$$
\mathrm{CaCO}_{3}(\mathrm{~s}) \rightarrow \mathrm{CaO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

## * Example: The Ideal-Gas Law (Solution)

When solid calcium carbonate $\left(\mathrm{CaCO}_{3}\right.$ is heated, it decomposes into solid calcium oxide ( CaO ) and carbon dioxide gas $\left(\mathrm{CO}_{2}\right)$. A small sample of $\mathrm{CaCO}_{3}$ is heated, and the carbon dioxide that evolves is collected in a $125-\mathrm{mL}$ flask. The gas collected in the flask has a pressure of 1.95 atm at a temperature of $45^{\circ} \mathrm{C}$. How many moles of $\mathrm{CO}_{2}$ gas were produced?

First, let's look at what we are given in the problem: $V=125 \mathrm{~mL}, \mathrm{P}=1.95 \mathrm{~atm}, \mathrm{~T}=45{ }^{\circ} \mathrm{C}$

What are we looking for? The moles ( $n$ ) of gas.
We need an equation that relates $P, V, n$, and $T$.
Use the Ideal Gas Law for this problem!

## 

When solid calcium carbonate $\left(\mathrm{CaCO}_{3}\right.$ is heated, it decomposes into solid calcium oxide ( CaO ) and carbon dioxide gas $\left(\mathrm{CO}_{2}\right)$. A small sample of $\mathrm{CaCO}_{3}$ is heated, and the carbon dioxide that evolves is collected in a $125-\mathrm{mL}$ flask. The gas collected in the flask has a pressure of 1.95 atm at a temperature of $45^{\circ} \mathrm{C}$. How many moles of $\mathrm{CO}_{2}$ gas were produced?

Let's convert all of our "givens" into the correct units for the Ideal Gas Law:

T needs to be in K: $45+273=318 \mathrm{~K}$
$V$ needs to be in $L$ : $125 m L\left(\frac{1 L}{1000 m L}\right)=0.125 L$
$P$ should be in atm (and it already is).

## *Example: The Ideal-Gas Law (Solution)

Calcium carbonate, $\mathrm{CaCO}_{3}(s)$, the principal compound in limestone, decomposes upon heating to $\mathrm{CaO}(s)$ and $\mathrm{CO}_{2}(g)$. A sample of $\mathrm{CaCO}_{3}$ is decomposed, and the carbon dioxide is collected in a 250-mL flask. After decomposition is complete, the gas has a pressure of 1.3 atm at a temperature of $31^{\circ} \mathrm{C}$. How many moles of $\mathrm{CO}_{2}$ gas were generated?

$$
\text { Use } P V=n R T
$$

Rearrange the equation to solve for moles ( $n$ ) of gas. Then plug everything into the equation.

$$
\mathbf{P V}=\mathbf{n R T}
$$

$$
\mathrm{n}=\frac{\mathrm{PV}}{\mathrm{RT}}=\frac{(1.95 \mathrm{~atm})(0.125 \mathrm{~L})}{\left(0.08206 \frac{\mathrm{~L} \mathrm{~atm}}{\mathrm{~mol} \mathrm{~K}}\right)(318 \mathrm{~K})}
$$

## *Example: The Ideal-Gas Law (Solution)

Calcium carbonate, $\mathrm{CaCO}_{3}(s)$, the principal compound in limestone, decomposes upon heating to $\mathrm{CaO}(s)$ and $\mathrm{CO}_{2}(g)$. A sample of $\mathrm{CaCO}_{3}$ is decomposed, and the carbon dioxide is collected in a $250-\mathrm{mL}$ flask. After decomposition is complete, the gas has a pressure of 1.3 atm at a temperature of $31^{\circ} \mathrm{C}$. How many moles of $\mathrm{CO}_{2}$ gas were generated?

Cancel the units to make sure that we get moles, then calculate.

$$
\mathbf{P V}=\mathbf{n R T}
$$

$$
\mathrm{n}=\frac{\mathrm{PV}}{\mathrm{RT}}=\frac{(1.95 \mathrm{~atm})(0.125 \mathrm{~L})}{\left(0.08206 \frac{\mathrm{~K} \text { atm }}{\mathrm{molK}}\right)(318 \mathrm{~K})}=0.0093 \mathrm{moles} \mathrm{CO}_{2} \text { gas }
$$
